Document Version:

Peer reviewed version

Please check the document version of this publication:

- A submitted manuscript is the version of the article upon submission and before peer-review. There can be important differences between the submitted version and the official published version of record. People interested in the research are advised to contact the author for the final version of the publication, or visit the DOI to the publisher's website.
- The final author version and the galley proof are versions of the publication after peer review.
- The final published version features the final layout of the paper including the volume, issue and page numbers.

Stimulators for Enhanced Resilience

- Redundancy: In technical terms, this means that certain components or functions are duplicated, so that the whole will continue to function properly if a component fails – the costs of redundancy must be assessed against the risk of failure/disruption
- Diversification of sources and customer profiles: variety of functions (living, working, industry, commerce, recreation) gives a better distribution in time for the energy needed and increased opportunities for interchange
- Hybrid systems: a combination of centralized with local supply (bottom-up or/and peer-to peer systems) gives fall back opportunities for local incidents and centralized infrastructure can be limited due to simultaneity advantage.

Current roadmaps for greening the supply

There is a lot of effort in PV, wind, bio-energy, heat pumps and electric transport.

Problems (among other disadvantages):

- Hinderance (f.i. wind-turbines)
- Spatial restrictions (for biomass production)
- Fluctuating supply not matching demand (for solar, wind)
- Fine dust in cities
- Efficiency losses due to conversion and transport
- High dependency and loads on E-grid

The need for changing in building related energy supply

So, the challenge for the energy transition proces is to:

- Save or generate by RES: 2.900 PetaJoule
- Eliminate: 185 mill. tons CO₂ per year

Within a time period of 33 years

884 PJ of gas consumption is distributed by the national gas grid to end-users

410 PJ of fossils is converted to electricity and distributed by the electricity grid

70 % of building related energy demand concerns **HEAT**

1 petajoule = 1,3 million PV panels =
55.000 roofs covered by PV

Sustainable residential renovation concepts

PASSIVE HOUSE

Installations

- Balanced venting with heat recovery
- No cooling
- All electric

Unresolved:
architecture, high investment, high level of disturbance, overheating, bad CoP of HP's

PASSIVE <--> SOLAR
in common:

Measures envelope

- More/less insulation

Installations

- Heat pump on outside air
 - Floorheating
 - PV solar panels
- Optional: Infrared heating
 - Electric boiler

SOLAR PV

Installations

- Natural venting
- Energy delivering

Unresolved:
architecture (glazed roofs), overheating, bad CoP of HP's, disbalance on E-grid

Resilience in Sustainable Urban Energy Supply Systems

Natural gas and other fossils are powerful and flexibel energy sources!

In order to maintain resilient supply, while phasing-out fossils, a number of considerations is to be applied:

- Small energy flows need **fast** reaction and **intelligent** controls;
- Build **redundancy** by exploiting multiple (green) sources and cloud-structured connections;
- Generate as much energy as possible **locally** as long as financially and spatial viable;
- Build **hybrid backup** on local energy clusters from national infrastructure
- Utilize **buffer** capacity of DHC-grids and connected buildings;
- Provide **cooling** capacity for high/well insulated buildings;
- Utilize optimal **cell balancing** (exchange of energy) by clustering multiple demand profiles and waste energy sources;
- Gain **low-hanging fruit** on building/area/regional/national levels;
- Promote **self-regulating** systems;
- Promote **end-user involvement**.
